G

In one embodiment, the object code that is being modified is stored in a class data structure according to the ~~Java~~ JAVA Virtual Machine Specification. Figure 3 is a symbolic representation of the class data structure which holds the code for a class. The term code is used to refer to all of the instructions, variables, definitions, pointers, addresses etc, that are stored in a class file and/or a class data structure. Magic item 202 supplies the magic number identifying the class file. The values of minor version 204 and major version 206 are the minor and major version numbers of the compiler that produced the class file. Constant pool count item 208 provides the number of entries in the constant pool. Constant pool 210 is a table of variable length structures representing various string constants, class names, field names, integers, floating point numbers and other constants that are referred to within the class file structure and its substructures. The value of access flags item 212 is a mask of modifiers used with class and interface declarations. The access flags modifiers are public, final, super, interface and abstract. The value of this class item 214 must be a valid index into the constant pool table. The constant pool entry at that index must be a structure representing the class or interface defined by this class file. For a class, the value of superclass item 216 either must be zero or must be a valid index into the constant pool. If the value of the superclass item is nonzero, the constant pool entry at that index must be a structure representing the superclass of the class defined by this class file.

The value of methods count item 226 provides the number of method_info structures in methods table 228. Each entry in methods table 228 must be a variable-length method_info structure providing a complete description of the ~~Java~~ JAVA Virtual Machine code for a method in the class or interface. The method_info structures represent all methods, both instance methods and, for classes, class (static) methods, declared by this class or interface type.

The value of the attributes count item 230 provides the number of attributes in attributes table 232. Each entry in attributes table 232 must be a variable-length attribute structure. A class data structure can have any number of attributes associated with it. More information about ClassFile formats and the ~~Java~~ JAVA Virtual Machine can be found in The ~~Java~~ JAVA Virtual Machine Specification, Tim Lindholm and Frank Yellin, Addison-Wesley, 1997, incorporated herein by reference.

The value of the access_flags item is a mask of modifiers used to describe access permission to and properties of a method. The access_flags modifiers are public, private, protected, static, final, synchronized, native, abstract and strict. The value of the name_index item must be a valid index into the constant pool. The constant pool entry at that index is a valid ~~Java~~ JAVA method name. The value of the descriptor_index item must be a valid index into the constant pool representing a valid ~~Java~~ JAVA method descriptor. The value of the attributes_count item indicates the number of additional attributes of this method. Each value of the attributes table must be a variable-length attribute structure. A method can have code attributes and exception attributes.

The Code attribute is a variable-length attribute used in the attributes table of method_info structures. A Code attribute contains the ~~Java~~ JAVA virtual machine instructions for a single ~~Java~~ JAVA method, instance initialization method or class interface initialization method.

In step 302 of Figure 5, the system accesses the beginning of the byte code for a particular method. In one implementation, step 302 includes accessing the first element in the code array of the code_attribute of the method_info structure. In step 304, the indices for the byte code are adjusted. That is, the system knows it needs to add code and knows how many bytes the code occupies. These bytes will be added to the array. Therefore, the remaining instructions need to be moved (change index) to make room for the new instructions. For example, if the start code needs 8 bytes, then the indices for the original code needs to be adjusted to reflect the displacement by 8 bytes. Additionally, all references to byte code within an instruction must also be adjusted; for example, the pointer reference for a jump or branch instruction must be adjusted. In step 306, new start code is added to the code array. An example of start code is code that starts a timer, tracer or other profiling mechanism. Some embodiments do not use start code. In step 308, the system accesses the end of the byte code, which in one embodiment is the end of the code array. In step 310, new exit byte code is added at the end of the code array. An example of exit code is code used to stop a timer, tracer or other profiling mechanism, as well as code to record information and/or perform action at the conclusion of a method. Some embodiments include adding all or a portion of the exit byte code at locations other than the end of the byte code. Step 310 also includes adding additional byte code to the code array that allows the return values and exceptions to be accessed. In step 312 of Figure 5, the exception table is adjusted. That is, because the indices of the byte codes changed, the values of start_pc, end_pc and handler_pc may need to be changed for existing exception handlers. Step 312 can also include adjusting other tables in the class file, as appropriate to the particular implementation. In step 314, a new entry is added to the exception table. This new entry correlates to the new AFinally@ block. The new entry has a catch_type of zero, indicating it is for all exceptions. Additionally, the new entry in the exceptions table will be added to the end of the exceptions table. The start_pc and end_pc of the new entry are set to include the original ~~Java~~ JAVA instructions for the method being modified. The value of the handler_pc for the new entry would point to the new byte code added in step 310.

Please replace the paragraph on page 17, lines ~~11-19~~ with the following amended paragraph:

Figure 6 is a flowchart describing more detail of the process of adding new exit byte code and the additional byte code for accessing return values and exceptions (step 310 of Figure 5). In step 402, new code is added to the code array to account for the situation where there is no exception. That is, the original ~~Java~~ JAVA method instructions are performed without any exceptions. After the original instructions are performed, the "Finally" block should be executed. The original code is modified to include a jump to the byte code subroutine for the AFinally@ block. Additionally, new byte code is added to access the return value and pass that return value to an object (or other structure, process, entity, etc.) for storage, statistical or other purposes.
